Cell Pathway: Ribosome:

Background: Ribosomes, the organelles that catalyze protein synthesis, consist of a small

> 40S subunit and a large 60S subunit. Together these subunits are composed of 4 RNA species and approximately 80 structurally distinct proteins. This gene encodes a cytoplasmic ribosomal protein that is a component of the 60S subunit. The protein belongs to the L22E family of ribosomal proteins. Its initiating

> methionine residue is post-translationally removed. The protein can bind specifically to Epstein-Barr virus-encoded RNAs (EBERs) 1 and 2. The mouse protein has been shown to be capable of binding to heparin. Transcript variants utilizing alternative polyA signals exist. As is typical for genes encoding ribosomal proteins, there are multiple processed pseudogenes of this gene dispersed

> through the genome. It was previously thought that this gene mapped to 3g26 and

that it was fused to the acute myeloid leukemia 1 (AML1

Function: miscellaneous:Binds to Epstein-Barr virus small RNAs and to

heparin., similarity: Belongs to the ribosomal protein L22e family.,
